

**Question 24** (4 marks)

In the margarine industry, alkenes are often hydrogenated to convert unsaturated oils into solid fats that have a greater proportion of saturated molecules.

- (a) Using ethene as an example, write an equation for this reaction and state the type of reaction this represents. 2

This is an addition reaction whereby the unsaturated ethylene molecule's double bond is broken, and two new single bonds formed to hydrogen atoms. This forms ethane.

- (b) Describe a test that could be used to confirm that all the ethene has been converted. 2

Unsaturated hydrocarbons discolour Bromine water,

as the  $\text{Br}_2(\text{aq})$  molecules give a distinctive colour

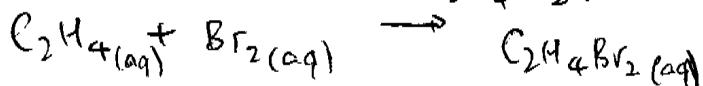

to water when in aqueous solution. As such, when

an unsaturated hydrocarbon such as ethylene is introduced

to  $\text{Br}_2(\text{aq})$ , it undergoes Halogenation (a type of

addition reaction), whereby  $\text{Br}_2(\text{aq})$  is broken down into

$2\text{Br}$ , and added across the double bond. This discolours the bromine water and forms  $\text{C}_2\text{H}_4\text{Br}_2$ .
